

FIRENET

Fire Alarm System

DigiFire™ is a Microsoft Windows® compatible application that provides a dynamic easy to use graphical PC interface for the F&SP Firenet fire alarm system.

The operator is able to fully monitor and control the system from the graphical user interface display (GUI) in accordance with pre-defined password controlled levels of access.

The program provides a series of interlinked maps such as the overall site plan and individual floor plans detailing the location and status of fire alarm detectors.

Maps can be generated using the tools provided, or imported and manipulated within the system.

Fire system components i.e. detectors, fire alarm panel cards and loops – displayed in the form of icons - change their status in accordance with the real time state of the fire alarm system.

The operator, using the tool bar buttons can move between the maps, zooming in or out in order to gain a better view of a detector icon or area.

Alternatively the system can be structured to automatically display selected maps in response to an alarm condition by way of pre-programmed parent/child relationships between these maps.

Pop-up menus for selected objects enable the operator (with the appropriate password authority) to monitor and control the system, including alarm acknowledgment and archiving.
